

Many small claims, all under active replication

Example Author A

2026-05-17

Abstract

A survey paper registering many small empirical claims about preprint discoverability. Each claim is currently the subject of an in-progress replication effort by an independent group.

1 Claims

Claim 1 (Claim 1). Preprint titles longer than 12 words receive 18% less cross-domain attention.
Replication status: untested.

Claim 2 (Claim 2). Adding a structured abstract correlates with 22% higher click-through from search.
Replication status: untested.

Claim 3 (Claim 3). Domain-experts cite within their own subfield 4x more than cross-domain.
Replication status: untested.

Claim 4 (Claim 4). Section-level retrieval beats whole-paper retrieval on recall@5 for narrow queries.
Replication status: untested.

Claim 5 (Claim 5). The reproducibility-budget signal is stable across three independent reannotation rounds.
Replication status: untested.

2 Notes

This document is a synthetic render of the canonical CIR for demonstration purposes. The full source, claim graph, and discussion live in the rrxiv reference instance. See the **rrxiv** protocol repository for the schema.
