

Retraction notices as first-class data

Abstract

Most preprint servers handle retractions as freeform text. We argue retractions should be structured artifacts linked to the specific claims they invalidate, with machine-readable rationale and an audit trail.

1 Claims

Claim 1 (Claim 1). Structured retraction notices reduce downstream citation contamination by an estimated 71%.

Replication status: untested.

Claim 2 (Claim 2). A retraction-as-annotation model is implementable without changing the underlying paper schema.

Replication status: untested.

2 Notes

This document is a synthetic render of the canonical CIR for demonstration purposes. The full source, claim graph, and discussion live in the rrxiv reference instance. See the **rrxiv** protocol repository for the schema.
