

# Many small claims, all under active replication

S. Iwasaki

2026-05-17

## Abstract

A survey paper registering many small empirical claims about preprint discoverability. Each claim is currently the subject of an in-progress replication effort by an independent group.

## 1 Claims

**Claim 1** (Claim 1). Preprint titles longer than 12 words receive 18% less cross-domain attention.  
*Replication status: untested.*

**Claim 2** (Claim 2). Adding a structured abstract correlates with 22% higher click-through from search.  
*Replication status: untested.*

**Claim 3** (Claim 3). Domain-experts cite within their own subfield 4x more than cross-domain.  
*Replication status: untested.*

**Claim 4** (Claim 4). Section-level retrieval beats whole-paper retrieval on recall@5 for narrow queries.  
*Replication status: untested.*

**Claim 5** (Claim 5). The reproducibility-budget signal is stable across three independent reannotation rounds.  
*Replication status: untested.*

## 2 Notes

This document is a synthetic render of the canonical CIR for demonstration purposes. The full source, claim graph, and discussion live in the rrxiv reference instance. See the **rrxiv** protocol repository for the schema.
